1. Explain what a loop is and why programmers use loops. Give one everyday example of something that repeats.

A loop is a kind of variable that stores one number. It runs only one time and then the program ends. Programmers use it to save memory.

2. What is an array? Write a short code example that creates an array of three numbers and prints each one using a loop.

An array is a function that sorts words into alphabetical order. Example: print(5) print(4) print(3).

3. Describe the difference between a for loop and a while loop. When would you choose each one?

A for loop and a while loop are exactly the same thing and you can use either one whenever you like. I do not know any difference between them.
